

The Average Times of First Flowering for Somerset Plants

BY WALTER WATSON, D.S.C., A.L.S.

FOR many years a Wild Flower Diary was kept, and in this the first dates on which the plants were seen in flower were given. This was done, partly for phenological reasons, but largely for the encouragement of those accompanying me in my field work. There was no intention of calculating the average time of first flowering during a number of years for each plant, but, later on, this was done for a particular reason. It was noticed that the flowering of the plants belonging to the families usually considered to be evolutionary early was conspicuous during the early parts of the year, whilst those belonging to the families considered to be of later evolution formed the major portion of the plants flowering in the later months. For example, the families of Ranunculaceæ and Cruciferæ had a greater number of species flowering in April and May, whereas in August and September the flowering species of Umbelliferæ and Compositæ were predominant. This seemed worthy of further attention and some methods of obtaining more definite comparisons of the flowering times of the various families were considered. For one of these methods the data in my Wild Flower Diary was used. The average time of first flowering during ten or more years, of most of our Somerset plants, was calculated. Then for each family the average time was obtained. For example, for the family Ranunculaceæ the average times of first flowering for 13 plants were added together and the total divided by 13. In a similar way the average times of first flowering were obtained for many other families. The results obtained were embodied in a paper on the possible evolutionary significance of flowering time and this was read to the Linnean Society on 4 January 1934.

The times given may be taken as fairly accurate for Somersetshire, though most of the field work was done in the Taunton area. For West Somerset the times are quite reliable, but as

those given for plants which only occur in East Somerset were obtained during excursions I cannot vouch for their absolute accuracy, as first flowering may have occurred previously to such excursions. Their reliability is, however, increased by the fact that flowering times were noted for more than ten years, and the calculations of the average times were made from the earlier dates. This was not necessary for their earlier purpose, so that the average times used for phylogenetic work do not always correspond to those given in this list. The Wild Flower Diary of the late W. D. Miller, who was the Hon. Secretary of our Botanical Society for about twenty years, was also consulted.

Some discrimination has been exercised in respect of some early flowering. For example, a few flowers of the greater stitchwort (our Somerset 'snapjacks') appear some time before general flowering begins. This is not unusual after a relatively mild winter, and it was found that this precocious flowering was on shoots which had not died down during the winter. A number of other similar instances can be given. In many cases the altitudes at which the records were made must be considered. Most plants flower much earlier at lower altitudes under similar conditions than at higher ones. In the Taunton district the oak in which the flowers are stalked is common at low levels, whilst the sessile-fruited oak only occurs on the hills. The flowers of the former usually appear a fortnight earlier than the latter. In the Roadwater woods the two oaks occur near one another and both appear in flower about the same time. Similar discrimination has been necessary in regard to other plants.

In addition to the average time of first flowering information has been given regarding the duration and optimum period of flowering. Some discrimination has been necessary for these and accelerated or retarded flowering has largely been ignored.

Column I gives the botanical names. These usually follow those given in the last London Catalogue, but as this dates from 1925 some emendations recommended in the *Journal of Ecology* (Vol. 33, No. 2; July 1946) have been adopted. For some genera which have been segregated into many species an aggregate name (indicated by 'agg.') has been used.

Column II gives the common name in general use.

Column III gives the average time of first flowering (date and month). In a few cases brackets are used. These indicate that the average times given may not be quite accurate as they depend on insufficient information owing to the observations being too few or for other reasons.

Column IV gives the usual duration of flowering in Somerset, the months (indicated by numbers) in which flowering is at its optimum being in thick type. The first month and the last month given for the duration of flowering does not necessarily mean that flowering occurs all through the respective months. Often the first flowering is in the latter part of the first month given and in the first part of the later month. Some plants as chickweed, daisy, dandelion, shepherd's purse, red dead-nettle, groundsel, Buxbaum's speedwell, annual poa, etc., can usually be found in flower throughout the year. Occasionally two periods of flowering occur. The thale cress, besides its early flowering period, may be found flowering much later if weather conditions are suitable. Dogwood often has a later period and many other instances of abnormal flowering could be given, whilst buttercups may be practically flowerless when July is hot and dry.
